

Question 4

1D Diffusion

The graphs for 1D Diffusion at timestamps $T=10, 100, 1000$ and $10,000$ is as follows:

As time progresses, the probability of the molecule being found at its initial position decreases and that of being found at the near boundary increases. This is expected as the gas diffuses.

2D Diffusion

The contour plots of probabilities at different time values and different cases are as follows:

Case 1 : $D_x > D_y$:

$$N = 10$$

N = 100

N = 1000

N = 10000

Case 2: $D_x < D_y$

N = 10

N = 100

N = 1000

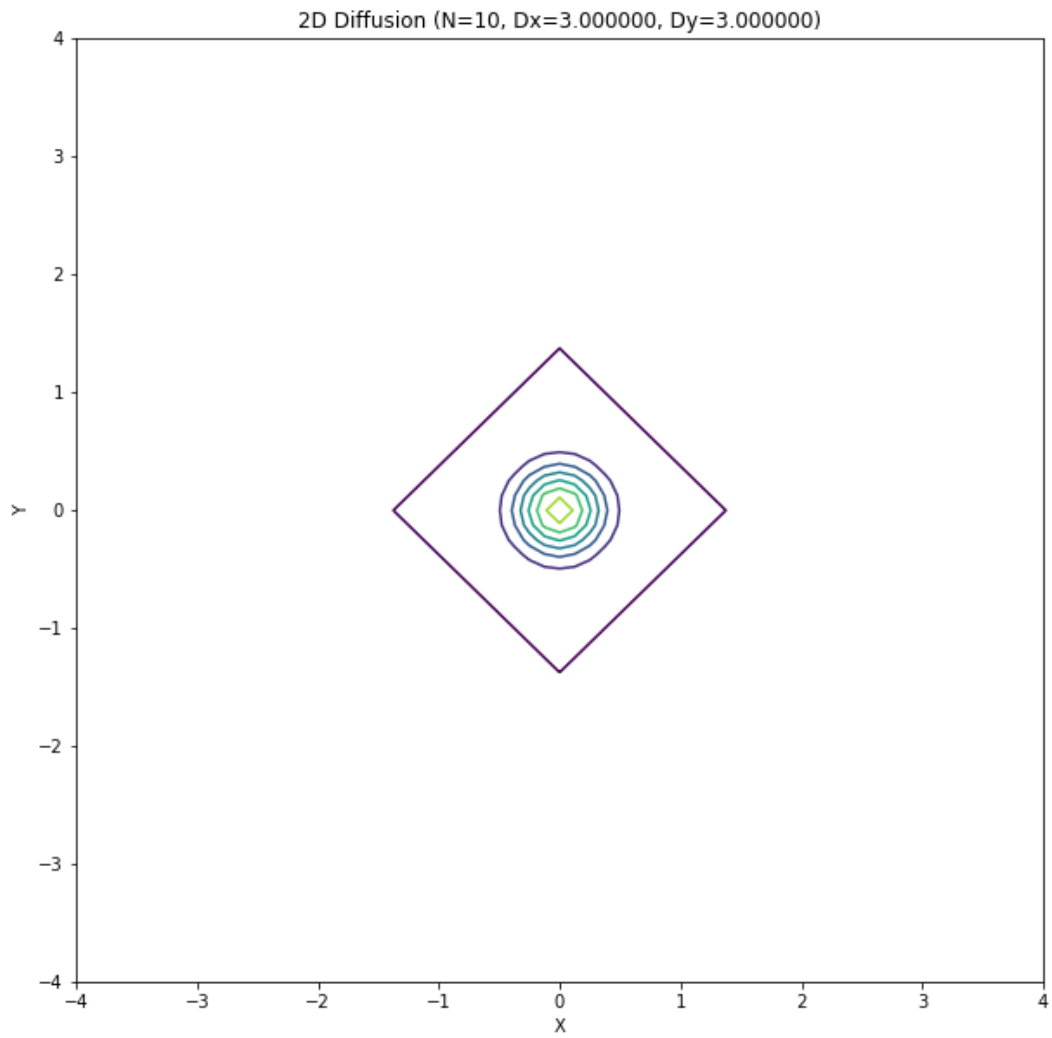

N = 10000

Case 3: $D_x = D_y$

N = 10

N = 100

N = 1000

N = 10000

From the graphs, it is understandable that the molecules spread over larger area as time progresses. The patterns spreads out more in the X direction if Dy is greater and more in the Y direction if Dx is greater.
